

MA388 Sabermetrics: Lesson 5

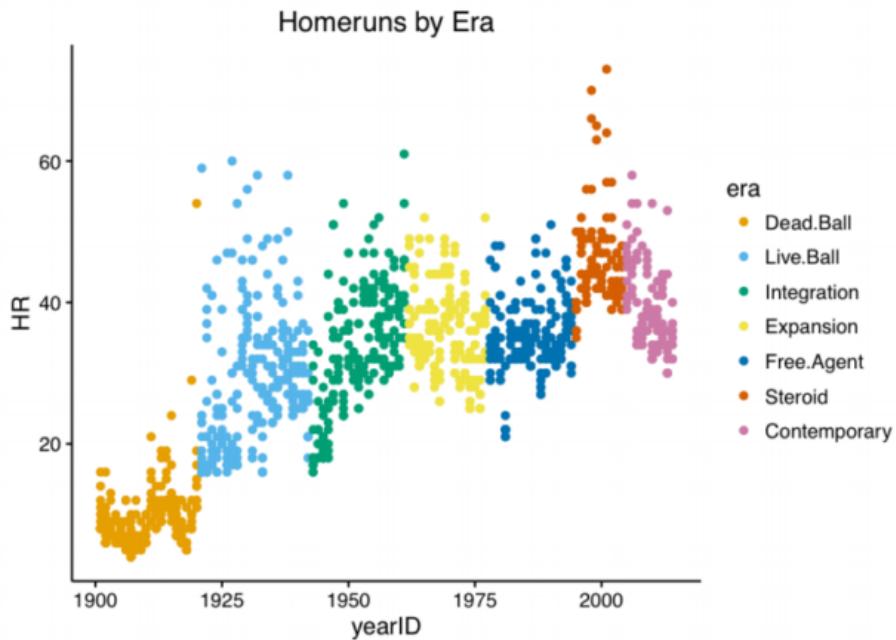

Introduction to R Graphics - Part II

LTC Jim Pleuss

```
library(Lahman)
library(tidyverse)
library(knitr)
```

Review:

I found the plot below [here](#). Let's recreate it! You can get part of the way there with what you already know.

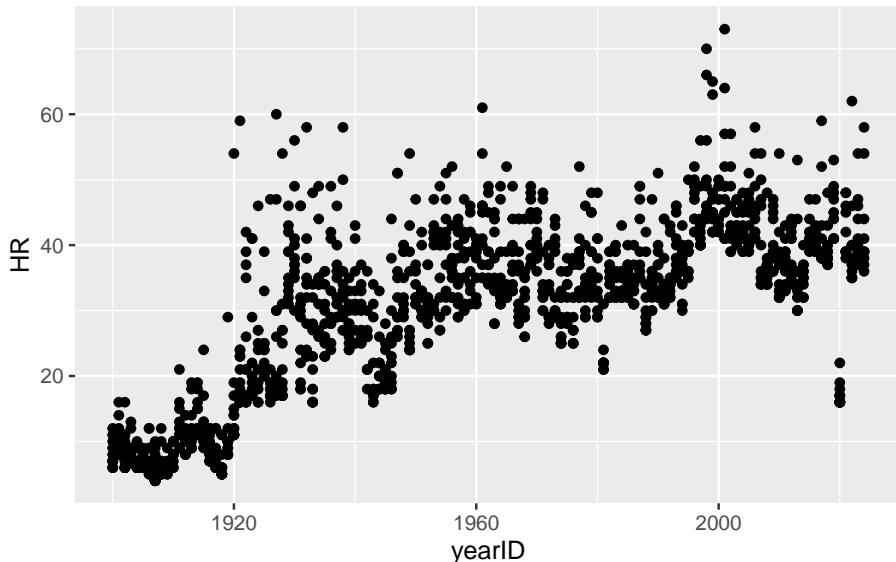

It will help you to know the dates that correspond to the beginning of different eras:

- 1900: Dead Ball
- 1920: Live Ball
- 1942: Integration
- 1961: Expansion
- 1977: Free Agent
- 1994: Steroid
- 2004: Contemporary

First, obtain the top-10 HR hitters for each year from 1900 to the present.

Let's plot what we have to far.

Not let's figure out how to color the points by era. We'll need to introduce a factor variable that represents dates according to their corresponding eras. See the example in ABDWR section 3.2.1 for an example of the `cut()` function.

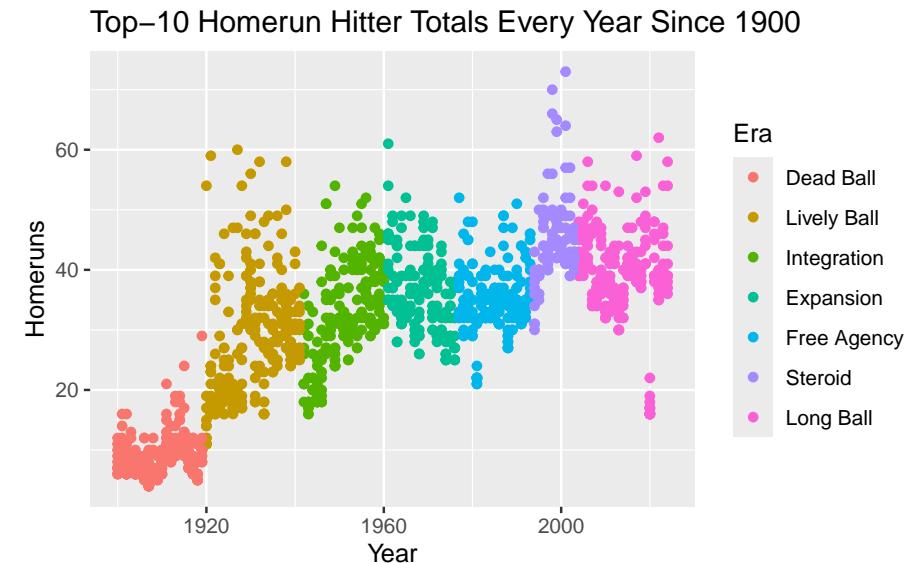

```
batting_df <- batting_df |>
  mutate(era = cut(yearID,
    breaks = c(1899, 1919, 1941, 1960, 1976,
              1993, 2003, 2050),
    labels = c("Dead Ball", "Lively Ball", "Integration",
              "Expansion", "Free Agency", "Steroid",
              "Long Ball"))
  )
  )
```

Let's see a sample of what our data frame looks like now:

```
batting_df |>  
slice_sample(n = 10)
```

```
yearID HR      era  
1 1984 32 Free Agency  
2 1932 41 Lively Ball  
3 1919 10 Dead Ball  
4 1903 7  Dead Ball  
5 1912 14 Dead Ball  
6 1975 38 Expansion  
7 2023 39 Long Ball  
8 2022 40 Long Ball  
9 2014 32 Long Ball  
10 1912 10 Dead Ball
```

Ready to add the color?

Factor Variables

Previously, we focused on scatter plots of two numeric variables. Now we are introducing factor variables. With factor variables we may wish to create univariate visualizations for each level of a factor – or perhaps multivariate visualizations for each level of a factor.

Example 1

Construct a boxplot of salaries by decade.

Here, the ‘factor’ is really the factor representation of a numeric variable:yearID. Don’t worry - we’re getting to a pure factor variable.

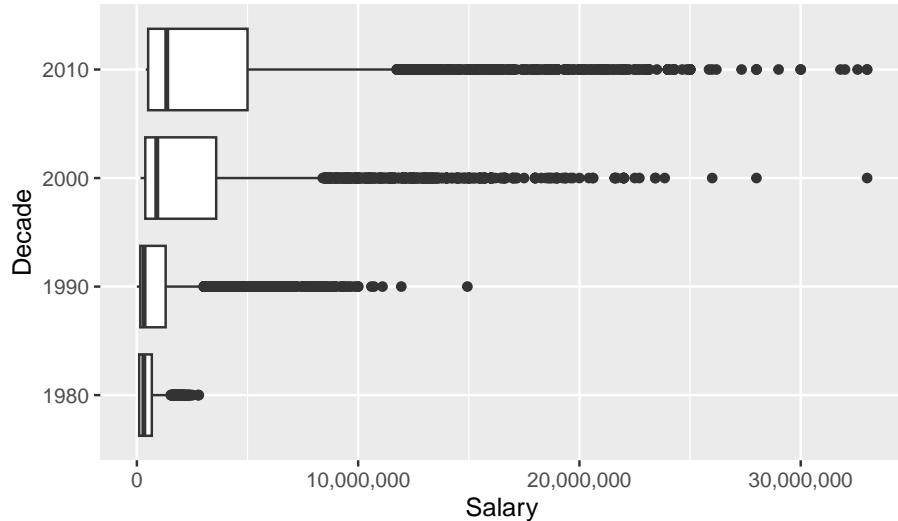

Let’s create a decade variable.

```
Salaries |>
  mutate(decade = floor(yearID / 10) * 10) |>
  head()
```

| | yearID | teamID | lgID | playerID | salary | decade |
|---|--------|--------|------|-----------|---------|--------|
| 1 | 2004 | SFN | NL | aardsda01 | 300000 | 2000 |
| 2 | 2007 | CHA | AL | aardsda01 | 387500 | 2000 |
| 3 | 2008 | BOS | AL | aardsda01 | 403250 | 2000 |
| 4 | 2009 | SEA | AL | aardsda01 | 419000 | 2000 |
| 5 | 2010 | SEA | AL | aardsda01 | 2750000 | 2010 |
| 6 | 2011 | SEA | AL | aardsda01 | 4500000 | 2010 |

```
Salaries |>
  mutate(decade = floor(yearID / 10) * 10) |>
  ggplot(aes(x = as.factor(decade), y = salary)) +
  geom_boxplot() +
  scale_y_continuous(labels = scales::comma) +
  labs(title = "MLB Salaries by Decade",
       y = "Salary",
       x = "Decade") +
  coord_flip()
```

MLB Salaries by Decade

Example 2

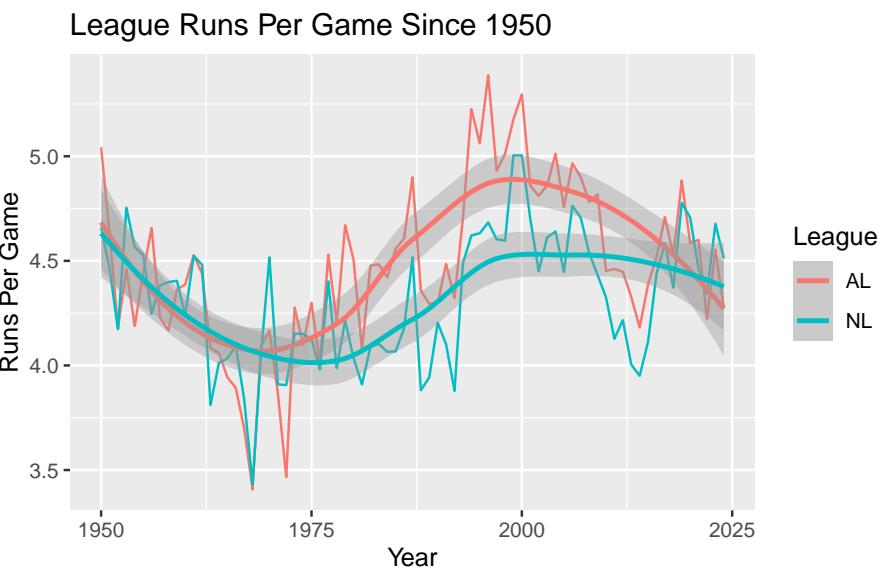

Determine the average runs scored per game (average team score, not two-team total score) by teams in Major League Baseball since 1950. Note any differences in American League and National League teams.

```
lg_rpg_df <- Teams |>
  select(yearID, lgID, R, G) |>
  filter(yearID >= 1950) |>
  group_by(yearID, lgID) |>
  summarize(RPG = sum(R) / sum(G))

head(lg_rpg_df)
```

```
# A tibble: 6 x 3
# Groups:   yearID [3]
  yearID lgID     RPG
  <int> <fct> <dbl>
1 1950  AL      5.04
2 1950  NL      4.66
3 1951  AL      4.63
4 1951  NL      4.46
5 1952  AL      4.18
6 1952  NL      4.17
```

```
lg_rpg_df |>
  ggplot(aes(x = yearID, y = RPG, color = lgID)) +
  geom_line() +
  geom_smooth() +
  labs(title = "League Runs Per Game Since 1950",
       x = "Year",
       y = "Runs Per Game",
       color = "League")
```

What jumps out at you in this figure?

In 2021, the Baseball Hall of Fame announced that no players received the minimum vote of 75% to be inducted. Famous players on the ballot included Barry Bonds, Roger Clemens, and Curt Schilling.

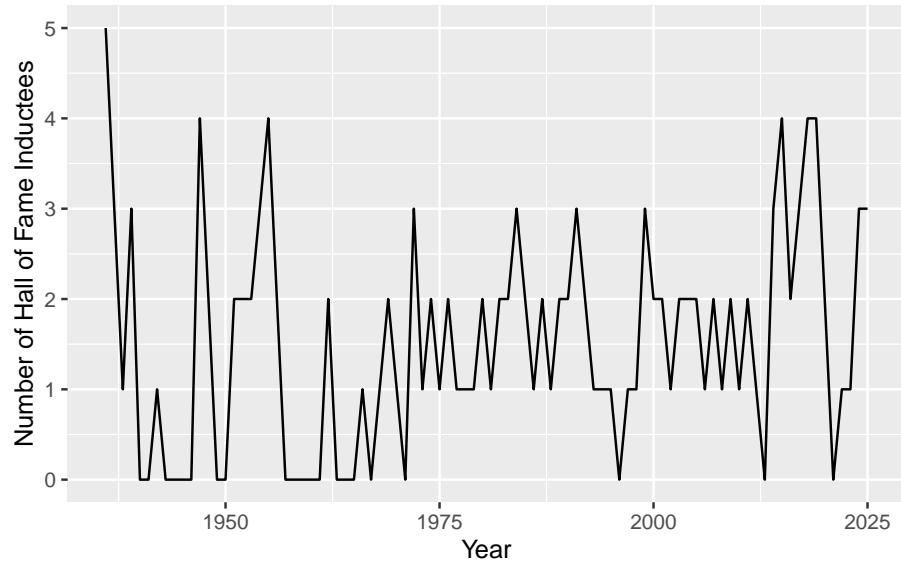

Using the `HallofFame` data frame in the `Lahman` package, plot the number of Hall of Fame inductees each year by the Baseball Writers Association of America (BBWAA) in the player category. Change the *y*-axis label to “Hall of Fame inductees” and *x*-axis to “year”. The `HallofFame` data frame contains a row for every year a player was voted on and whether he was inducted.

Suggested steps:

- Filter the data frame to contain only inducted players (`inducted == "Y"`, `category == "Player"`, `votedBy == "BBWAA"`) (*provided below*).
- Determine how many players were inducted each year (*provided below*).
- Plot the number of inducted players by year.

```
# Number of inductees by year.
yearlyHF <- HallOfFame |>
  filter(inducted == "Y",
         category == "Player",
         votedBy == "BBWAA") |>
  count(yearID)

# Unfortunately, yearlyHF data frame does not contain years with no inductees.
# We can join it with another data frame containing all the years and replace
# NAs with 0s.
yearlyHF <- yearlyHF |>
  full_join(data.frame(yearID = 1940:2022)) |>
  mutate(n = replace_na(n,0))
```

Roger Clemens and Curt Schilling have been on the ballot for the Hall of Fame several times. After not being selected for a 10th time in 2022, they were removed from the ballot.

Clemens and Schilling

Figure 1: Roger Clemens

Figure 2: Curt Schilling

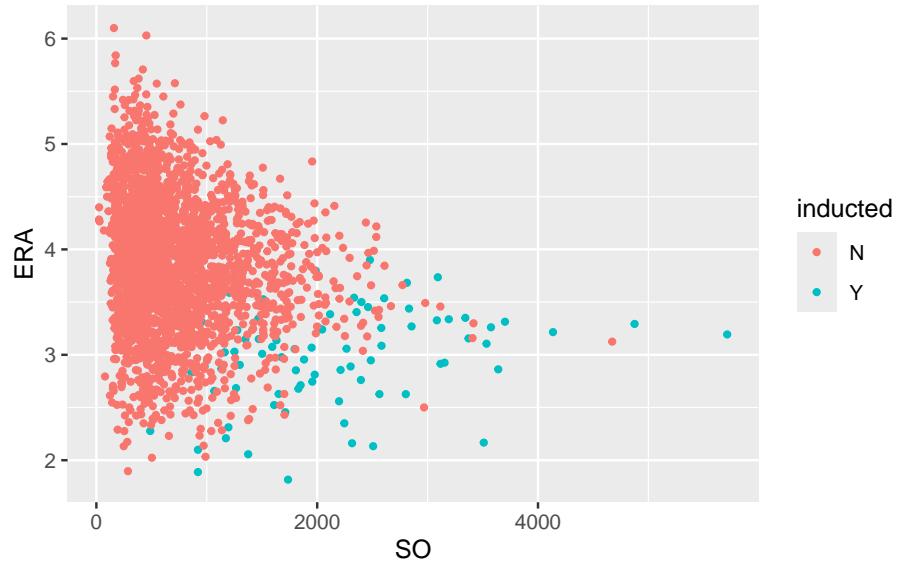

First, let's create a data set containing all pitchers with an indicator of whether they are in the Hall of Fame.

```
# Get career wins, earned run average, and strikeouts.
careers <- Pitching |>
  group_by(playerID) |>
  summarize(W = sum(W),
             ER = sum(ER),
             IPouts = sum(IPouts),
             SO = sum(SO)) |>
  mutate(ERA = 9*ER/(IPouts/3)) |>
  filter(IPouts/3 > 500)

# Add whether they were inducted in the Hall of Fame.
careers <- HallOfFame |>
  filter(inducted == "Y",
         category == "Player") |>
  select(playerID, inducted) |>
  right_join(careers) |>
  mutate(inducted = replace_na(inducted, "N"))
```

Let's look at career strikeouts by whether or not they were inducted.

```
careers |>
  ggplot(aes(x = SO, y = ERA, color = inducted)) +
  geom_point(size = 1)
```

Let's figure out where Clemens and Schilling are.

```
library(ggrepel)
clemschil <- careers |>
  filter(playerID %in% c("clemero02", "schilcu01"))

careers |>
  ggplot(aes(x = SO, y = ERA, color = inducted)) +
  geom_point() +
  geom_text_repel(data = clemschil,
                  aes(x = SO, y = ERA, label = playerID),
                  show.legend = FALSE)
```

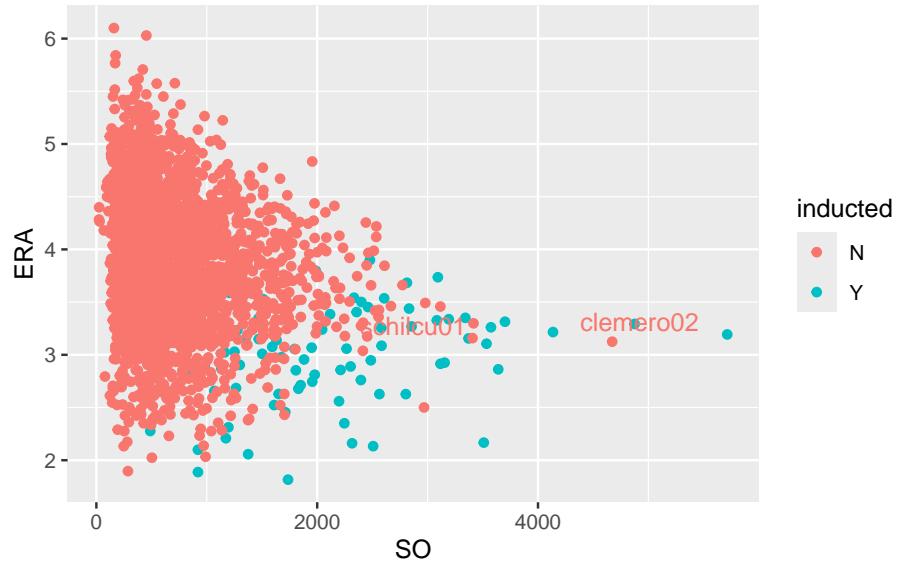

Figure 3: ERA vs. SO by Hall of Fame status for pitchers with at least 500 innings pitched.

Your Turn

In the last figure, there is an uninducted player with about 2500 strikeouts and a 2.5 ERA. Determine who that player is and add his playerID to the plot above.
